Week 11 - Introduction to Modeling, part 2

1. Lesson - No lesson this week

2. Weekly graph question

In [6]:
```
import pandas as pd
import numpy as np
from sklearn.ensemble import RandomForestRegressor
from sklearn.metrics import root_mean_squared_error
from sklearn.model_selection import GridSearchCV
from sklearn.metrics import make_scorer
from sklearn.pipeline import make_pipeline
from sklearn.preprocessing import StandardScaler
from sklearn.model_selection import RepeatedKFold
from sklearn.model_selection import cross_val_score
from sklearn.metrics import classification_report
```

The book names one of Vonnegut's rules as "keep it simple" and another as "have the guts to cut." Here is some data from the previous week's lesson. If you had to cut one of the two plots below, which would it be? Which seems more interesting or important? Explain. (Should "amount of training data used" or "number of estimators" be on the x-axis.)

In [7]:
```
np.random.seed(0)
num_points = 10000
feature_1a = np.random.random(size = num_points) * 3
feature_2a = np.random.random(size = num_points) * 3
feature_3a = np.random.random(size = num_points) * 3
train_target = (feature_1a - 2 * feature_2a) * feature_3a + np.random.
feature_1b = np.random.random(size = num_points) * 3
feature_2b = np.random.random(size = num_points) * 3
feature_3b = np.random.random(size = num_points) * 3
test_target = (feature_1b - 2 * feature_2b) * feature_3b + np.random.n
train_df = pd.DataFrame({"f1": feature_1a, "f2": feature_2a, "f3": fea
test_df = pd.DataFrame({"f1": feature_1b, "f2": feature_2b, "f3": feat
rf = RandomForestRegressor()
rf.fit(train_df.values, train_target)
```

Out[7]:

```
▾ RandomForestRegressor
▶ Parameters
```

In [8]:

```
rmse_lst = list()
rf = RandomForestRegressor()
for x in range(round(num_points / 20), num_points, round(num_points /
    rf.fit(train_df.values[0:x,:], train_target[0:x])
    rmse_lst.append(root_mean_squared_error(rf.predict(test_df.values)

import matplotlib.pyplot as plt
```

In [9]:

```
plt.plot(rmse_lst)
plt.xlabel("Amount of training data used (20 = max)")
plt.ylabel("Loss function")
```

Out[9]:

```
Text(0, 0.5, 'Loss function')
```

In [10]:

```
num_trees_lst = list()
for n_estimators in range(1, 100, 3):
    rf = RandomForestRegressor(n_estimators = n_estimators)
    rf.fit(train_df.values, train_target)
    num_trees_lst.append(root_mean_squared_error(rf.predict(test_df.va
```

In [11]:

```
plt.plot(num_trees_lst)
```

```
plt.xlabel("Number of estimators (trees)")
plt.ylabel("Loss function")
```

Out[11]: Text(0, 0.5, 'Loss function')

If I had to cut one of the plots, I would remove the Number of estimators plot. We can see past around 5 estimators, the performance does not increase much. Therefore the plot is not very informative beyond understanding that we do not need many estimators to minimize the loss.

3. Working on your datasets

This week, you will do the same types of exercises as last week, but you should use your chosen datasets that someone in your class found last semester. (They likely will not be the particular datasets that you found yourself.)

Here are some types of analysis you can do:

- Implement a random forest model.
- Perform cross-validation.
- Tune hyperparameters.
- Evaluate a performance metric.

If you like, you can try other types of models, too (beyond linear regression and random forest) although you will have many opportunities to do that next semester.

In [12]:
```
df = pd.read_csv('Milestone 3 EDA/ibm_hi_small_trans_cleaned.csv')
df
```

Out[12]:

4. Storytelling With Data plot

Reproduce any graph of your choice in chapter seven (p. 165-185) of the Storytelling With Data book as best you can. You do not have to get the exact data values right, just the overall look and feel.
